## 21 ABSTRACT

22 Pandrug-resistant (PDR) *K. pneumoniae* has been reported sporadically in many  
23 countries and remains rare in Brazil. The lack of genomic studies limits the  
24 comprehension of the determinants mostly involved with the PDR emergence in *K.*  
25 *pneumoniae*. This study aimed to unravel the main genetic determinants involved with  
26 the PDR background of a clinical ST11 *K. pneumoniae* recovered in the Brazilian  
27 Amazon region. The carbapenem-resistant Kp196 was submitted to WGS and its  
28 intrinsic and acquired resistome was assessed by CARD and comparison with wild-type  
29 genes. Kp196 resistome was composed of acquired resistance determinants and  
30 mutations in chromosomal genes. Among the formers, *bla*<sub>CTX-M-15</sub> and *bla*<sub>NDM-1</sub>, *bla*<sub>OXA-</sub>  
31 *9*, *bla*<sub>OXA-1</sub>, *aadA1*, *aacA4*, *strAB*, *aph(3')-VI*, *aac(3)-IId*, *qnrS1*, *qnrB1*, *oqxAB*, *dfrA14*,  
32 *sul2*, *catB3* were found in the vicinity of mobile genetic elements, which could  
33 contribute to their spread. Kp196 colistin resistance was multifactorial and attributed to  
34 modifications in ArnT (M114L/V117I/R372K), PhoQ (D150G), and the *mgrB*  
35 disruption by IS*Kpn25*. Besides the presence of *qnr* and *oqxAB* genes, Kp196 also  
36 presented altered GyrA (S83I) and ParC (S80I). An *in-block* deletion in the repressor  
37 RamR, contributing to *acrAB* overexpression, and the presence of an enhanced-function  
38 AcrB variant (S966A), probably led to the Kp196 multidrug and tigecycline resistance.  
39 Insertions, *in-block* deletion, and missense mutations were involved with *ompK35-36-*  
40 *37* inactivation, also accounting for the Kp196 multidrug resistance, including  
41 carbapenems. The Kp196 PDR profile, especially the carbapenem resistance, was due to  
42 the accumulation of different mechanisms, in which modifications in housekeeping  
43 genes accounted for a more stable resistome.

44

45 Keywords: PDR - tigecycline resistance - colistin resistance - *ompK* - *acrAB* -  
46 untreatable bacteria.

47

## 48 **1. Introduction**

49 Pandrug resistance is related to the non-susceptibility to all agents in all antimicrobial  
50 categories considered approved and useful for treating an infection caused by a specific  
51 organism [1]. *Klebsiella pneumoniae* is featured by a remarkable propensity for  
52 multidrug resistance acquisition, and infections caused by multidrug- (MDR) and  
53 extensively drug-resistant (XDR) strains are highly prevalent worldwide, while pandrug  
54 resistance (PDR) remains rare [2]. These MDR/XDR lineages are frequently  
55 carbapenem-resistant, and in this case, tigecycline and colistin remain the unique  
56 effective therapeutic choices [3]. Therefore, tigecycline and colistin co-resistance in  
57 carbapenem-resistant *K. pneumoniae* may result in apparently untreatable organisms,  
58 leading to a worrisome impact on clinical outcomes. Eventually, strains of the  
59 international high-risk clonal complex CC258 (ST11, ST437, and ST258) have  
60 presented the PDR profile. In Brazil, so far, PDR *K. pneumoniae* has only been reported  
61 in a few CC258 strains in the South/Southeast Brazilian regions [4-6], however, the  
62 genomic features involved with the PDR manifestation were rarely assessed. Here, the  
63 complete genome sequence of a clinical PDR *K. pneumoniae* strain, KP196, recovered  
64 in the Brazilian Amazon region was unraveled, and the main genetic determinants  
65 involved with the PDR background were revealed.

66

## 67 **2. Material and Methods**

68           The Kp196 was recovered in 2022 in a clinical setting in the Amazon Region  
69 (Maranhão). The antimicrobial susceptibility test (AST) was determined for all  
70 antibiotics considered for *Enterobacteriaceae* resistance classification [1], and  
71 interpreted according to the Clinical and Laboratory Standards Institute (CLSI) [7], and  
72 European Committee on Antimicrobial Susceptibility Testing (EUCAST) (for  
73 tigecycline and polymyxins) guidelines [8].

74           The Kp196 genome was obtained on the Illumina Hiseq 2500 using Nextera  
75 paired-end library kit for library construction. SPAdes assembler v3.15.2 was used for  
76 genome assembling [9]. Gene prediction/annotation was conducted with Prokka v1.14.6  
77 [10]. Core genome MLST (cgMLST) was determined in Bacterial Isolate Genome  
78 Sequence Database (BIGSdb; <http://bigsdb.pasteur.fr/klebsiella/>). The Comprehensive  
79 Antibiotic Resistance Database (CARD) was used for antimicrobial resistance gene  
80 (ARG) prediction [11]. Plasmid replicon identification was conducted with the  
81 PlasmidFinder [12]. The deduced protein of each Kp196 chromosomal gene involved  
82 with resistance was compared with that of the wild-type reference strains *K.*  
83 *pneumoniae* NTUH-K2044 (**NC 012731.1**) and MGH 78578 (**CP000647**). The Kp196  
84 genome sequence was deposited in the GenBank under accession no.  
85 **JAQOSS000000000** and with BioProject no. **PRJNA926954**.

86

### 87 **3. Results and Discussion**

88           The in vitro analyses revealed that Kp196 corresponded to a PDR strain (Table  
89 1), and the cgMLST assigned it to the ST11 pandemic lineage. In spite of the high  
90 prevalence of this lineage in Brazil [13], this is the first report of a PDR ST11 in the

91 country. In fact, PDR *K. pneumoniae* remains rare in Brazil, having only been reported  
92 in ST437 and ST258 restricted to the South/Southeast regions [4-6].

93 The PDR phenotype was in accordance with the Kp196 expressive resistome,  
94 which was composed of genes associated with resistance to  $\beta$ -lactams (*bla*<sub>SHV-11</sub>, *bla*<sub>CTX-M-15</sub>,  
95 *bla*<sub>OXA-9</sub>, *bla*<sub>OXA-1</sub>, *bla*<sub>TEM-1</sub>), aminoglycosides (*aadA1*, *aacA4*, *strAB*, *aph(3')*-VI,  
96 *aac(3)-IIId*), carbapenems (*bla*<sub>NDM-1</sub>) fluoroquinolones (*qnrS1*, *qnrB1*, *oqxAB*),  
97 trimethoprim (*dfrA14*), sulfonamides (*sul2*), tetracycline (*tetD*), fosfomycin (*fosA5*) and  
98 chloramphenicol (*catB3*). All these genes were flanked or in the vicinity of insertion  
99 sequences and plasmid-related genes. In fact, Kp196 harboured *repA*, *repB* and *repE*  
100 genes from IncFIB and IncR plasmids. The exception was the *tetD*, *fosA5*, and *bla*<sub>SHV-11</sub>,  
101 which were chromosomally encoded.

102 Regarding the intrinsic mechanisms, mutations were observed in genes involved  
103 with resistance to fluoroquinolones (*gyrA*, *parC*), colistin (*mgrB*, *arnT*, *phoQ*),  
104 tigecycline (*ramR*), and multiple drugs including carbapenems and cephalosporins  
105 (*acrB*, *ompK35*, *ompK36*, and *ompK37*). Ciprofloxacin is effective and widely used for  
106 treating ESBL-producing *K. pneumoniae* infections. The Kp196 presented substitutions  
107 in the quinolone resistance-determining region (QRDR) of GyrA (S83I) and ParC  
108 (S80I), which are involved with ciprofloxacin resistance emergence in *K. pneumoniae*.

109 Colistin resistance in *K. pneumoniae* is mainly associated with modifications in  
110 *pmrAB*, *phoPQ*, *mgrB*, and *arnT* genes [14]. Among these genes, substitutions were  
111 found in the deduced protein of ArnT (M114L, V117I, and R372K), involved with  
112 *pmrA* transcription, and in PhoQ (D150G). Besides, the *mgrB* was disrupted by  
113 IS*Kpn25* at the nucleotide position 133, leading to the production of a truncated and  
114 inactive MgrB protein, probably contributing to Kp196 colistin resistance due to *phoPQ*

115 derepression [14]. Interestingly, this same alteration was previously found in colistin-  
116 resistant ST258 *K. pneumoniae* from Greece and Brazil [15], indicating that this region  
117 might be a hotspot for IS*Kpn25* insertion. This IS additionally carried *bla*<sub>TEM-1</sub>, *aac*(3)-  
118 *IId*, and a complete Restriction modification System (RMS), also contributing to  $\beta$ -  
119 lactams and aminoglycosides resistance, and to host protection from foreign DNA  
120 infection. Therefore, the Kp196 colistin resistance could be associated with the  
121 accumulation of multiple alterations in chromosomal genes (*mgrB*, *arnT*, and *phoQ*). In  
122 this case, even upon restoration of the canonical function by reversal mutations in one  
123 of these genes, Kp196 would retain the colistin resistance (Table 2).

124 In spite of several tetracycline resistance mechanisms already described, *K.*  
125 *pneumoniae* tetracycline-resistant strains remain rare [15]. Among these mechanisms,  
126 efflux pump overexpression (*acrAB* and *oqxAB*) due to alterations in their regulatory  
127 genes (*ramR*, *ramA*, *soxR*, *soxS*, *marA*, *marR*, *acrR*, *oqxR*, *rarA*) is the most common  
128 [16]. From all the aforementioned regulatory genes, only *ramR* (*ramA* repressor), *oqxR*  
129 and *rarA* (*oqxAB* repressor and activator, respectively) were altered in Kp196. The  
130 RamR presented two amino acid modifications (V19A and T119H) and a 14 bp-deletion  
131 downstream the nt 330 was present in this gene, leading to a frameshift. This *in-block*  
132 deletion probably generated an inactivated RamR, resulting in *ramA* derepression and,  
133 consequently, to *acrAB* overexpression. The substitutions found in RarA (Q172R and  
134 V191I) have not been described yet, while the OqxR presented the V130A alteration  
135 that had already been found in tetracycline-susceptible strains [16]. Therefore, the *ramR*  
136 alterations were probably the main tetracycline and multidrug resistance determinant in  
137 Kp196 (Table 2).

138 Kp196 harboured the S966A AcrB variant, which is involved with the increment  
139 of drug transport efficiency, conferring an increased ability to persist/resist its substrate  
140 antibiotics when overexpressed [17]. Since *acrAB* is also involved with resistance to  
141 other tetracyclines, fluoroquinolones, erythromycin,  $\beta$ -lactams, chloramphenicol, and  
142 also carbapenems [18-20], the *acrAB* overexpression with an enhanced-function AcrB  
143 variant may also contribute with the remarkable Kp196 multidrug resistance phenotype.

144 In *K. pneumoniae*, loss of the two major outer membrane porins OmpK35 and  
145 OmpK36 enhances the multidrug resistance in ESBL-producing strains, increasing  
146 resistance to carbapenems, broad-spectrum cephalosporins, fluoroquinolones,  
147 tetracycline, and chloramphenicol [21]. In Kp196, the *ompK35* suffered a deletion at  
148 nucleotide 338 resulting in a frameshift, while an *in-block* deletion from nucleotide 164  
149 to 687 disrupted *ompK36*. The *ompK37* is normally expressed only in *ompK35-36*-  
150 deficient strains, slightly influencing carbapenem resistance [21]. However, in addition  
151 to *ompK35/36*, the *ompK37* of Kp196 was also altered, presenting a set of SNPs and  
152 insertions along the gene, leading to a defective porin. Therefore, all three *K.*  
153 *pneumoniae* major porins were inactivated in Kp196, contributing significantly to  
154 multidrug resistance in this strain. Finally, considering the clinical relevance of  
155 carbapenem resistance, this study stressed the multifactorial and overrepresented  
156 mechanisms in Kp196, which comprised the presence of *bla<sub>NDM-1</sub>* and alterations of  
157 several intrinsic genes, such as *acrAB*, *ompK35-36-37*.

158 Interestingly, the unique genomic studies on CC258 *K. pneumoniae* PDR strains  
159 in Brazil demonstrated a different resistome composition compared to Kp196,  
160 considering both the intrinsic and acquired resistance determinants involved with PDR

161 manifestation [4,6]. Besides, in both studies, the PDR phenotype was mainly due to the  
162 presence of acquired resistance genes.

163

#### 164 **4. Conclusion**

165 Here, a clinical strain was described in the Amazon region likely presenting a more  
166 stable resistome, since multiple mutations in chromosomal genes, which are not easily  
167 lost as the acquired resistance determinants, importantly contributed to the observed  
168 PDR phenotype.
