 **Vision:** Journal of Biomedical Research & Environmental Sciences main aim is to enhance the importance of science and technology to the scientific community and also to provide an equal opportunity to seek and share ideas to all our researchers and scientists without any barriers to develop their career and helping in their development of discovering the world.

RESEARCH ARTICLE

Low Prevalence of Transmitted HIV-1 Antiretroviral Resistance in Pregnant Women from Rio de Janeiro, Brazil

Jose Carlos Couto-Fernandez* and Carlos Silva de Jesus#

Laboratory of AIDS and Molecular Immunology, WHO Reference Center for the Surveillance of HIV-1 Resistance (HIVResNet), Oswaldo Cruz Institute-IOC/FIOCRUZ, Rio de Janeiro-RJ, Brazil

ABSTRACT

Background: HIV screening during antenatal care is being expanded in Brazil for early diagnosis of HIV-1 infection during pregnancy and prevention of vertical transmission. HIV genotyping in pregnant women is crucial to reduce the risk of vertical transmission in those carrying resistant strains and may also be used for Transmitted Drug Resistance (TDR) surveillance purpose. We evaluated prevalence and patterns of HIV-1 TDR and HIV-1 subtype distribution, in recently diagnosed ARV naive pregnant women from Rio de Janeiro, Brazil.

Methods: 299 blood samples of recently diagnosed HIV-1-infected pregnant women from four reference antenatal care public health units in Rio de Janeiro, were consecutively collected and analyzed from 2005 to 2015. Viroseq™ (Abbott) and Trugene™ HIV-1 Genotyping Systems (Siemens) were used for genotyping and the Stanford Algorithm for Interpretation of HIV-1 Resistance for TDR and subtype identification.

Results: The most prevalent HIV-1 subtype was the subtype B (79.3%), followed by subtype F (11.9%), BF recombinant forms (4%), subtype C (2%) and the recombinant forms: CRF02_AG, CRF31_BC, K/F and DF identified in one subject each. Overall, the associated resistance mutations were 12.6%, 4.3% associated to the Nucleoside Reverse Transcriptase Inhibitors (NRTIs) of the samples, 4.9% to Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs) and 3.4% to Protease Inhibitors (PIs). Mutations associated with NRTI resistance were TAMs, F77L, M184V; associated with NNRTI resistance were K103N, Y188H and L100I and mutations associated to PIs were D30N, M46I, and V82L.

Conclusion: HIV-1 subtype B was the most prevalent subtype observed in our study. For the first time infections with the circulating recombinant forms CRF02_AG and CRF31_BC were described in a pregnant woman, suggesting the spread of African derived virus in Brazil and the introduction in Rio de Janeiro of the CRF31_BC coming from South Brazil. Our results strongly suggest the need of establishing a regular surveillance system for transmitted HIV-1 drug resistance in pregnant women in Brazil and its integration in antenatal care management policies for HIV-1 infected women should be considered.

Introduction

The HIV/AIDS epidemic in Brazil is increasingly affecting women, mainly by heterosexual transmission and a considerable portion of HIV-1 diagnoses occurs during the pregnancy [1]. Serological screening for HIV/AIDS during prenatal care has been expanded in Brazil (Ordinance No. 993, of 09/04/2000), for the early diagnosis of HIV-1 infection during gestation and the prevention of vertical transmission [2].

The knowledge of the HIV-1 Transmitted Drug Resistance (TDR) in this vulnerable population is essential to avoid vertical transmission and to guide Antiretroviral Therapy (ART) in pregnant women [3]. Since 2012, HIV-1 genotyping testing has been available to infected pregnant women, before and during ART. Considering

J Biomed Res Environ Sci. 2022 Sep 15; 3(9): 1054-1056. doi: 10.37871/jbres1554, Article ID: JBRES1554, Available at: <https://www.jelsciences.com/articles/jbres1554.pdf>

the gradual increase in the TDR among the drug-naïve HIV-1 infected population, the knowledge of HIV diversity and transmitted resistance in pregnant women is crucial to avoid vertical transmission, in those carrying resistant strains and to monitor the transmission of transmitted drug resistance in Brazil [2,3].

The objective of the present molecular epidemiologic study was to evaluate the prevalence and patterns of HIV-1 resistance mutations, as well as HIV-1 subtype distribution, in recently diagnosed antiretroviral drug-naïve pregnant women from Rio de Janeiro, Brazil.

Methods

A total of 299 blood samples from recently diagnosed HIV-1-infected pregnant women, were received from 4 reference public health units specialized on antenatal care in Rio de Janeiro, Brazil. The samples were consecutively collected and analyzed for the evolution of HIV-1 TDR during January 2009 to June 2015 in the AIDS and Molecular Immunology Laboratory from Oswaldo Cruz Institute-IOC/FIOCRUZ, Rio de Janeiro, Brazil. A quantitative of 197 subjects were previously evaluated from 2005 to 2008 [4] and the 102 samples were consecutively collected from 2009 to 2015. The genotyping of protease and reverse transcriptase HIV-1 genes was determined using Viroseq™ HIV-1 Genotyping System (Celera-Abbott Molecular, US) from 2002 to 2007 and Trugene™ HIV-1 Genotyping Assay (Siemens Healthcare, GR), were used during 2008 to 2015, as methodologies for the genotyping of HIV-1 drug resistance mutations.

The determination of the viral subtype was performed using the Stanford Algorithm for the Assessment of HIV-1 Resistance to ARVs [5] and confirmed through phylogenetic analysis, using the bioinformatics tool MEGA v.7.0 [6].

Transmitted resistance mutations were evaluated in the CPR tool (hivdb.stanford.edu) and according to the WHO list for TDR [7].

Results

The most prevalent HIV-1 subtype in the series was the HIV-1 subtype B (79.3%), followed by F1 subtype (11.9%), BF recombinant forms (4%) and subtype C (2%). Circulating recombinant forms CRF02_AG and CRF31_BC and single recombinants (URFs) K/F and D/F were identified in the samples (Figure1).

A total, of 12.6% (37 samples) display at least one associated resistance mutations or related polymorphisms. The prevalence of transmitted resistance to antiretroviral drugs were 4.2% (CI: 3.6%-5.2%), 4.3% for NRTIs, 4.9% for NNRTIs and 3.4% for PIs.

In the recent evaluation (2009 to 2015), TDR mutations associated to Protease Inhibitors (PI) were found in 3 (2.9%) samples. Resistance mutations associated to PIs were D30N, M46I, and V82L. Mutations associated with resistance to NRTIs were present in 8 (7.8%) of the samples, including three Timidine Associated Mutations (TAMs) and 4 samples (3.9%) to Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs). NRTI mutations were K103N, Y181C, T188H and L100I detected in one infected woman each (Table 1).

Discussion

HIV-1 subtype B was the most prevalent among HIV-1 infected, drug-naïve pregnant women from Rio de Janeiro State, although a high proportion of the F1 subtype infections were observed in infections in women compared to previous published data of HIV-1 subtypes in patients falling ART [8]. For the first time a CRF02_AG infection was described in a pregnant woman, suggesting the spread of this CRF in

Brazil [9]. Indeed, the presence of CRF31_BC and CRF02_AG in pregnant women suggests a recent introduction and dissemination of these recombinant forms, originating respectively from African countries and southern Brazilian states [10]. Phylogenetic analysis of HIV-1 genotyping sequences proved to be effective in studying the molecular epidemiology of HIV-1 in Brazil [11,12].

Significant majors HIV-1 transmitted resistance mutations were observed, mainly to NNRTIs and PIs, including third generation PIs as tipranavir and darunavir. In addition, time trend analysis showed a significant increase in the prevalence of TDR to RT inhibitors, probably due to their wide use over the time in Brazil [4,13]. The prevalence of mutations to NRTI and PIs were generally low. The results reinforce the maintenance of the pre-therapy genotyping test in HIV-positive pregnant women, for the implementation of treatment, reduction of the risk of vertical transmission and development of HIV-1 resistance.

Our results strongly suggest the need of establishing a regular surveillance system for transmitted HIV-1 drug resistance in pregnant women in Brazil. HIV-1 genotyping before starting therapy in pregnant women may reduce a significant proportion of vertical transmission in Brazil, and its integration in antenatal care management policies for HIV-1 infected women should be considered.
